VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

Bachelor of Technology

Engineering Economics

Unit III: Production

Production: Factors of Production, Concepts of cost, Break even Analysis, Law of variable Proportions, Internal and External Economies of scale, Depreciation.

(05 Hours)

❖ Production

Production refers to the process of creating goods or services by transforming inputs (resources such as raw materials, labour, and capital) into outputs that satisfy human needs and wants. It involves combining resources effectively and efficiently to generate products or services that add value.

In **economic engineering**, production focuses on integrating economic principles with engineering practices to optimize resource use, improve efficiency, and maximize value. It examines the technical and financial aspects of the production process to achieve the most cost-effective and sustainable outcomes.

Elements of Production

1. **Inputs (Factors of Production):**
   - **Land:** Natural resources used in production (e.g., minerals, water, land area).
   - **Labour:** Human effort, skills, and expertise.
   - **Capital:** Machinery, tools, and buildings used to produce goods and services.
   - **Entrepreneurship:** The ability to organize resources and take risks to start or manage production.
2. **Transformation Process:**

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

- The process of converting inputs into outputs through various techniques, methods, and operations (e.g., manufacturing, assembly, or service delivery).

3. **Outputs:**
   - The finished goods or services ready for consumption or further processing.
4. **Technology:**
   - The methods, machinery, and tools used to enhance productivity and efficiency in the production process.
5. **Value Addition:**
   - Production increases the value of inputs by creating goods or services that are more useful and desirable.

Types of Production

1. **Primary Production:**
   - Involves extracting natural resources (e.g., agriculture, fishing, mining).
2. **Secondary Production:**
   - Involves manufacturing and industrial processes that transform raw materials into finished goods.
3. **Tertiary Production:**
   - Focuses on providing services (e.g., retail, healthcare, education).
4. **Quaternary Production:**
   - Involves knowledge-based services like research, technology, and data analysis.

Examples of Production

1. **Manufacturing Industry:**
   - Applying automation and Lean Manufacturing principles to reduce costs and improve production flow.
2. **Energy Production:**
   - Optimizing the design and operation of power plants to maximize energy output while minimizing costs and environmental impact.
3. **Construction Projects:**
   - Efficiently managing resources like materials and labour to complete infrastructure projects within budget and timelines.
4. **Agricultural Production:**

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

- Using advanced techniques like precision farming to optimize crop yield and reduce waste.

5. **Software Development:**
   - Managing the development process to deliver high-quality software efficiently and cost-effectively.

❖ Factors of Production

Factors of production are the resources used to produce goods and services. They are the building blocks of economic activity and are categorized into four main types: **Land, Labour, Capital, and Entrepreneurship.** These resources are combined and utilized in various ways to create outputs that satisfy human needs and wants.

In **economic engineering**, the factors of production are analysed, optimized, and managed to maximize efficiency and minimize costs. The integration of economic principles and engineering practices provides a systematic approach to resource allocation, production planning, and decision-making.

Factors of Production

1. **Land (Natural Resources):**
   - Refers to all natural resources available for production.
   - Includes raw materials such as minerals, oil, forests, water, air, and land area.
   - Land is a **fixed supply** resource, meaning its availability is limited.
   - Examples:
     - Agricultural land for farming.
     - Oil fields for energy production.
     - Forests for timber and paper production.
   - Economic Importance:
     - The value of land depends on its location, fertility, and the type of resource it holds.
     - Rent is the income earned from land.
2. **Labour (Human Resources):**
   - Represents the human effort (physical and mental) used in production.
   - Includes workers, managers, and all levels of expertise required to operate production systems.
   - Factors Affecting Labour:

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	**1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities.** **2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program.** **3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.**

        - Education, skills, training, and health of the workforce.
        - Productivity, which measures output per unit of labour input.
    - Economic Importance:
        - Wages and salaries are the rewards for labour.
        - Highly skilled labour contributes to innovation and efficiency.
3. **Capital:**
    - Refers to man-made resources used in the production process.
    - Includes tools, machinery, buildings, vehicles, and technology.
    - Types of Capital:
        - **Physical Capital:** Tangible assets like equipment and infrastructure.
        - **Human Capital:** Knowledge and skills acquired by the workforce.
        - **Financial Capital:** Money used to acquire physical and human capital.
    - Economic Importance:
        - Interest or profit is the income generated from capital.
        - Investments in capital improve productivity and long-term economic growth.
4. **Entrepreneurship:**
    - Refers to the ability to combine land, labour, and capital effectively to create goods or services.
    - Entrepreneurs take risks to innovate, manage production, and make decisions that drive economic activity.
    - Economic Importance:
        - Entrepreneurs earn profits as a reward for their risk-taking and innovation.
        - They contribute to economic growth by introducing new technologies and creating jobs.

❖ Concepts of Cost

The **concepts of cost** refer to various measures and classifications of cost used to analyse and manage financial aspects of production and decision-making. Understanding these concepts helps businesses and organizations make informed decisions regarding pricing, budgeting, resource allocation, and profitability.

Costs are broadly classified into several categories depending on their behaviour, purpose, and context.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

In **economic engineering**, cost concepts are applied systematically to optimize production, design, and financial decisions. Economic engineering emphasizes analysing, modelling, and minimizing costs while maintaining efficiency and effectiveness.

Concepts of Cost

1. **Cost Optimization**:
   - Economic engineering focuses on achieving the lowest cost for a given output level while maintaining quality and functionality.
   - Tools like linear programming, cost-benefit analysis (CBA), and value engineering are applied.
2. **Life-Cycle Costing (LCC)**:
   - Considers the total cost of ownership over the product's life cycle, including:
     - Initial costs (design, manufacturing).
     - Operating and maintenance costs.
     - Disposal or recycling costs.
3. **Direct and Indirect Costs**:
   - **Direct Costs:** Directly attributable to a specific project or product (e.g., raw materials, labour).
   - **Indirect Costs:** Cannot be traced directly (e.g., administrative expenses, facility utilities).
   - Economic engineering ensures accurate cost allocation to improve budgeting.
4. **Activity-Based Costing (ABC)**:
   - Allocates costs based on specific activities that drive costs.
   - Example: Machine setup costs allocated based on the number of setups.
   - Importance:
     - Helps identify high-cost activities and areas for improvement.
5. **Break-Even Analysis**:
   - Determines the production level at which total revenue equals total costs.
   - Break-
     even Point (units)=Fixed CostsPrice per unit - Variable Cost per unit\text{Break-even Point (units)} = \frac{\text{Fixed Costs}}{\text{Price per unit - Variable Cost per unit}}Break-
     even Point (units)=Price per unit - Variable Cost per unitFixed Costs.
   - Application:
     - Helps in pricing and capacity planning decisions.
6. **Capital and Operating Costs**:

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

- **Capital Costs:** Long-term investments in assets (e.g., machinery, buildings).
- **Operating Costs:** Day-to-day costs of running a production system.
- Economic engineering balances these costs for efficient system design.

7. **Cost of Quality (CoQ)**:
   - Considers costs related to quality, including:
     - Prevention costs (training, quality assurance systems).
     - Appraisal costs (inspections, testing).
     - Failure costs (defects, rework).
8. **Depreciation and Amortization**:
   - Allocation of the cost of tangible and intangible assets over time.
   - Economic engineering uses these for budgeting and cost projection.

Applications of Cost

1. **Manufacturing Optimization**:
   - Use marginal cost analysis to determine optimal production levels.
   - Apply activity-based costing to streamline processes.
2. **Project Management**:
   - Use incremental cost analysis to decide between project alternatives.
   - Apply life-cycle costing for long-term investments.
3. **Energy Systems**:
   - Analyse the total cost of ownership for renewable energy systems.
   - Minimize operating costs using predictive maintenance.
4. **Supply Chain Management**:
   - Reduce logistics costs using route optimization and inventory control.
   - Balance fixed and variable costs in transportation.
5. **Product Design**:
   - Incorporate cost-benefit analysis in product features and functionality.
   - Use value engineering to reduce costs without compromising performance.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

❖ Break-Even Analysis

Break-even analysis is a method to find the point at which total revenue equals total costs. At this point, a business makes no profit or loss; it simply "breaks even."

1. **Fixed Costs (FC):** Costs that stay constant, no matter how much you produce (e.g., rent, salaries).
2. **Variable Costs (VC):** Costs that change with production levels (e.g., raw materials, electricity).
3. **Selling Price (SP):** Price at which each unit is sold.
4. **Contribution Margin:** The amount left after subtracting variable costs from the selling price:
   Contribution Margin per Unit=Selling Price per Unit−Variable Cost per Unit

Advantages of Break-Even Analysis:

1. Simple and easy to understand.
2. Helps in decision-making for pricing and production.
3. Useful for financial planning and risk management.

Limitations of Break-Even Analysis:

1. Assumes all products are sold at the same price.
2. Assumes costs remain constant, which may not be realistic.
3. Does not consider changes in market demand or external factors.

Applications of Break-Even Analysis:

1. **Start-ups:** To decide if a business idea is viable.
2. **Pricing Strategy:** To determine the selling price for profitability.
3. **Cost Management:** To evaluate the impact of changes in fixed or variable costs.
4. **Product Planning:** To compare different production scenarios.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

❖ Law of Variable Proportion

The **Law of Variable Proportion** explains how the output of a production process changes when the quantity of one input (like labour) is varied while keeping other inputs (like land or machinery) constant. It shows how adding more units of a variable input affects total and marginal output.

1. **Fixed Input:** An input that remains constant (e.g., land, machinery).
2. **Variable Input:** An input that can be changed (e.g., labour, raw materials).
3. **Total Product (TP):** Total output produced.
4. **Marginal Product (MP):** The additional output from adding one more unit of the variable input.
5. **Average Product (AP):** Output per unit of the variable input:

Three Stages of the Law:

1. **Stage 1: Increasing Returns to the Variable Input**
   - Adding more of the variable input increases total output at an increasing rate.
   - Marginal product (MP) increases because the fixed input is underutilized.
   - Example: Hiring more workers on a farm increases output quickly as resources are better utilized.
2. **Stage 2: Diminishing Returns to the Variable Input**
   - Adding more of the variable input increases total output, but at a **decreasing rate**.
   - Marginal product (MP) starts to decline but remains positive.
   - This stage is the most efficient and productive.
   - Example: Too many workers on the same land start crowding, and their efficiency reduces.
3. **Stage 3: Negative Returns to the Variable Input**
   - Adding more of the variable input causes total output to **decline**.
   - Marginal product (MP) becomes negative.
   - Example: Overcrowding of workers leads to inefficiency, and output starts to decrease.

Importance of the Law:

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

1. **Efficient Resource Allocation:** Helps businesses decide the optimal number of variable inputs to maximize output.
2. **Cost Management:** Identifies the point where adding more inputs leads to inefficiency.
3. **Production Planning:** Useful in determining the scale of production.

Limitations:

1. Assumes only one variable input, which may not be realistic in complex production systems.
2. Does not apply when technology changes or new innovations occur.
3. Focuses on short-term production and does not consider long-term effects.

Example:

- A farmer has a fixed piece of land (fixed input).
- Variable input: Labour (workers).
- Initially, as more workers are hired, output increases quickly (Stage 1).
- Later, the increase slows down as the land becomes crowded (Stage 2).
- Eventually, too many workers lead to inefficiency, and output decreases (Stage 3).

❖ Internal and External Economies of Scale

Economies of scale refer to the cost advantages that a business experiences as it grows larger. These advantages occur when the cost per unit of production decreases due to an increase in production scale. They are classified into two types: **Internal Economies of Scale** and **External Economies of Scale**.

1. Internal Economies of Scale

Internal economies of scale occur within a company as it expands its production. These result from the efficient use of resources and improved operational processes.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

Types of Internal Economies:

1. **Technical Economies:**
   - Large-scale businesses can afford advanced machinery and technology, which increases efficiency.
   - Example: Automating production lines reduces per-unit costs.
2. **Managerial Economies:**
   - Larger firms can hire specialized managers for various departments, leading to better decision-making and efficiency.
   - Example: Hiring experts for marketing, finance, and production.
3. **Purchasing Economies:**
   - Bulk buying of raw materials or supplies reduces the cost per unit.
   - Example: A large company buying in bulk from suppliers gets discounts.
4. **Marketing Economies:**
   - Spreading marketing costs (like advertisements) over a larger output reduces cost per unit.
   - Example: National TV ads benefit a larger audience for the same cost.
5. **Financial Economies:**
   - Large firms can access cheaper loans or funding because of their established credibility.
   - Example: Lower interest rates on bank loans for large businesses.
6. **Risk-Bearing Economies:**
   - Larger companies can spread risks by diversifying products or markets.
   - Example: A company selling both summer and winter goods can balance seasonal demand.

2. External Economies of Scale

External economies of scale occur outside the company but benefit all firms within a specific industry or region. These advantages are due to the growth and development of the industry as a whole.

Types of External Economies:

1. **Infrastructure Development:**
   - Improved infrastructure (roads, ports, utilities) reduces operational costs for all firms in the region.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

- Example: A new highway reduces transportation costs for nearby businesses.

2. **Skilled Labour Availability:**
   - As an industry grows, the local workforce becomes more skilled, reducing training costs for companies.
   - Example: IT hubs attract skilled software engineers.
3. **Supplier Network:**
   - Industry growth attracts suppliers, creating competition among them and reducing input costs.
   - Example: A car manufacturing hub attracts tire and component suppliers.
4. **Research and Development (R&D):**
   - Industry-wide R&D benefits all companies by introducing new technology and practices.
   - Example: Renewable energy R&D benefits all solar panel manufacturers.
5. **Government Support:**
   - Governments may provide subsidies, tax breaks, or other incentives to promote a specific industry.
   - Example: Subsidies for electric vehicle manufacturers.

Key Differences Between Internal and External Economies:

Aspect	Internal Economies	External Economies
Where it Occurs	Within a single company	Across an entire industry or region
Controlled By	The individual company	Industry growth and external factors
Examples	Bulk buying, better management	Improved infrastructure, skilled labor

Importance of Economies of Scale:

1. **Cost Reduction:** Lower production costs lead to higher profit margins.
2. **Competitive Advantage:** Larger firms can offer lower prices than smaller competitors.
3. **Market Expansion:** Reduced costs allow companies to enter new markets or increase production.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

Limitations of Economies of Scale:

1. **Diseconomies of Scale:** Beyond a certain size, a company may face inefficiencies like poor communication or high bureaucracy.
2. **Dependence on External Factors:** External economies depend on factors outside the company's control, such as government policies or industry trends.

Example:

- A car manufacturer (Internal):
  - Buys materials in bulk, hires specialists, and automates assembly lines.
- The automotive industry (External):
  - Benefits from government tax incentives and improved transportation networks in the region.

❖ Depreciation

Depreciation is the gradual reduction in the value of a fixed asset over time due to wear and tear, aging, or obsolescence. It is a way to allocate the cost of an asset over its useful life.

1. **Why Depreciation Happens:**
   - Regular use of the asset (e.g., machinery, vehicles).
   - Natural aging and deterioration.
   - Technology becoming outdated.
2. **Purpose of Depreciation:**
   - To spread the cost of an asset over its useful life.
   - To show the true value of assets in financial statements.
   - To calculate expenses and reduce taxable income.
3. **Assets That Depreciate:**
   - Tangible assets like buildings, vehicles, machinery, and equipment.
   - **Exception:** Land does not depreciate because it typically does not lose value.

Methods of Depreciation:

1. **Straight-Line Method:**
   - Depreciation is the same every year.

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities. 2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program. 3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.

- Formula: Annual Depreciation=Cost of Asset−Salvage Value/Useful Life

2. **Declining Balance Method:**
   - Higher depreciation in earlier years and lower in later years.
3. **Units of Production Method:**
   - Depreciation is based on how much the asset is used.

Example: Straight-Line Method

- **Asset:** A computer
- **Cost of Asset:** $10,000
- **Salvage Value:** $2,000
- **Useful Life:** 5 years

Step 1: Calculate Annual Depreciation

Annual Depreciation=10,000−2,000/5=1,600

Step 2: Depreciation Schedule

- Year 1: $1,600
- Year 2: $1,600
- Year 3: $1,600
- Year 4: $1,600
- Year 5: $1,600

At the end of 5 years, the total depreciation will be $8,000, and the asset will have a salvage value of $2,000.

Advantages of Depreciation:

1. **Accurate Financial Reporting:** Reflects the true value of assets over time.
2. **Cost Allocation:** Spreads the expense of assets, matching costs to revenues.
3. **Tax Benefits:** Depreciation is treated as an expense, reducing taxable income.

Limitations of Depreciation:

VISION	MISSION
To be recognized as an Excellent Innovative Engineering Department through Academic Programme which develops leaders in Education and Research in Computer Science	**1. To create self-learning environment by facilitating leadership qualities, team-spirit and ethical responsibilities.** **2. To strengthen department-industry collaboration and interaction with professional society through technical knowledge and internship program.** **3. To promote research and development with current techniques through well qualified resources in the area of computer science and wireless engineering.**

1. **Estimation Involved:** Useful life and salvage value are assumptions and may not be precise.
2. **No Cash Impact:** It is a non-cash expense and does not directly affect cash flow.
3. **Market Value Not Reflected:** Depreciation does not account for changes in market value.
